Gene Symbol Krt17

Gene Full Name keratin 17, type I

Background This gene encodes the type I intermediate filament chain keratin 17, expressed in nail bed, hair follicle,

sebaceous glands, and other epidermal appendages. Mutations in this gene lead to Jackson-Lawler type

pachyonychia congenita and steatocystoma multiplex. [provided by RefSeq, Aug 2008]

Function Type I keratin involved in the formation and maintenance of various skin appendages, specifically in

determining shape and orientation of hair (By similarity). Required for the correct growth of hair follicles, in particular for the persistence of the anagen (growth) state (By similarity). Modulates the function of TNF-alpha in the specific context of hair cycling. Regulates protein synthesis and epithelial cell growth through binding to the adapter protein SFN and by stimulating Akt/mTOR pathway (By similarity). Involved in tissue repair. May be a marker of basal cell differentiation in complex epithelia and therefore indicative of a certain type of epithelial "stem cells". Acts as a promoter of epithelial proliferation by acting a regulator of immune response in skin: promotes Th1/Th17-dominated immune environment contributing to the development of basaloid skin tumors (By similarity). May act as an autoantigen in the immunopathogenesis of psoriasis, with certain peptide regions being a major target

for autoreactive T-cells and hence causing their proliferation. [UniProt]

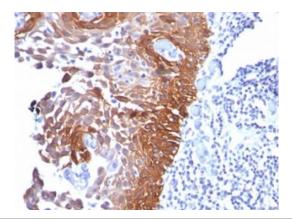

Calculated Mw 48 kDa

PTM Phosphorylation at Ser-44 occurs in a growth- and stress-dependent fashion in skin keratinocytes, it has

no effect on filament organization.

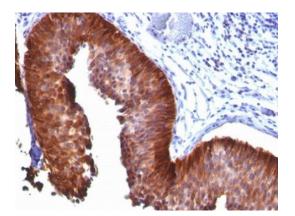

Cellular Localization Cytoplasmic
