## Bioinformation

Gene Symbol	IL7R
Gene Full Name	interleukin 7 receptor
Background	The protein encoded by this gene is a receptor for interleukine 7 (IL7). The function of this receptor requires the interleukin 2 receptor, gamma chain (IL2RG), which is a common gamma chain shared by the receptors of various cytokines, including interleukine 2, 4, 7, 9, and 15. This protein has been shown to play a critical role in the V(D)J recombination during lymphocyte development. This protein is also found to control the accessibility of the TCR gamma locus by STAT5 and histone acetylation. Knockout studies in mice suggested that blocking apoptosis is an essential function of this protein during differentiation and activation of T lymphocytes. The functional defects in this protein may be associated with the pathogenesis of the severe combined immunodeficiency (SCID). Alternatively spliced transcript variants have been found for this gene. [provided by RefSeq, May 2014]
Function	Receptor for interleukin-7. Also acts as a receptor for thymic stromal lymphopoietin (TSLP). [UniProt]
Calculated Mw	52 kDa
PTM	N-glycosylated IL-7Ralpha binds IL7 300-fold more tightly than the unglycosylated form. [UniProt]
Cellular Localization	Isoform 1: Cell membrane; Single-pass type I membrane protein. [UniProt]
